

A Radiometer for a Stochastic Background of Gravitational Radiation

Robert Ward
for the
LIGO Scientific Collaboration

Amaldi 7
Sydney, Australia
July 2007

Signals from cosmological sources and astrophysical foregrounds

Characterized by gravitational wave spectrum

$$\Omega_{\text{GW}}(f) = \frac{f}{\rho_c} \frac{d\rho_{\text{GW}}}{df}$$

Approximate by power law in LIGO band

$$\Omega_{\text{GW}}(f) = \Omega_{\alpha} \left(\frac{f}{100 \text{ Hz}} \right)^{\alpha}$$

Also see presentations by J. Whelan and B. Whiting

LIGO-G070406-00-Z 2

Isotropic Search: Average over the whole sky

Cross Correlation Estimator

$$Y = \int_{-\infty}^{+\infty} df \tilde{s}_1^*(f) \tilde{s}_2(f) \tilde{Q}(f)$$

With a variance

$$\sigma_Y^2 \approx \frac{T}{2} \int_0^{+\infty} df P_1(f) P_2(f) |\tilde{Q}(f)|^2$$

Using an Optimal Filter

$$\tilde{Q}(f) = \frac{1}{N} \frac{\gamma(f) \Omega_t(f)}{f^3 P_1(f) P_2(f)}$$

Assuming a Source Strain Spectrum

$$\Omega_t(f) = \Omega_\alpha (f/100 \text{ Hz})^\alpha$$

$\gamma(f)$ = Overlap Reduction Function

S4 Science Run, H1L1+H2L1:

$H_0 = 72 \text{ km/s/Mpc}$

51-150 Hz (includes 99% of inverse variance)

$\Omega_0 \pm \sigma\Omega = (-0.8 \pm 4.3) \times 10^{-5}$

90% Bayesian UL: 6.5×10^{-5}

GW Radiometer Motivation

- Stochastic GW Background due to Astrophysical Sources?
 - Not isotropic if dominated by nearby sources
 - ➔ Do a ***Targeted Stochastic Search*** with LIGO
 - Source position information from
 - Signal time delay between different sites (sidereal time dependent)
 - Sidereal variation of the single detector acceptance
- ➔ **Time-Shift and Cross-Correlate!**
- ➔ Effectively a Radiometer for Gravitational Waves

The Radiometer

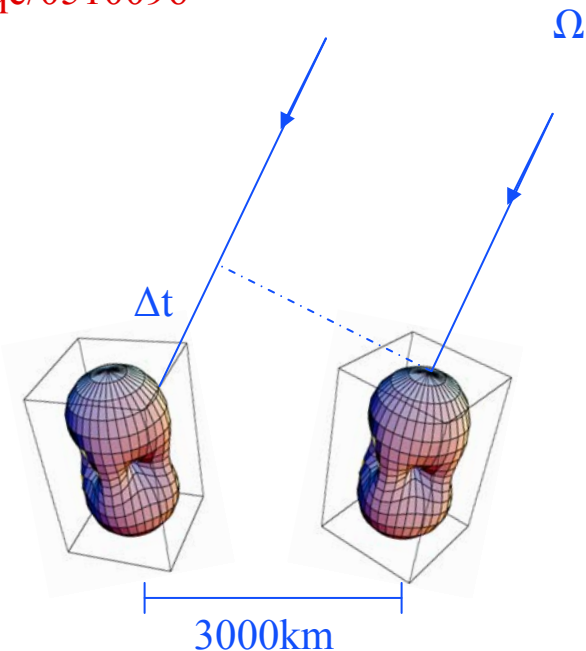

$$Y(\Omega) = \int dt \int dt' s_1(t) s_2(t') \tilde{Q}_{t_{\text{sidereal}} \Omega}(t - t')$$

$$\sigma^2(\Omega) \approx \frac{T}{4} (Q_{t_{\text{sidereal}} \Omega}, Q_{t_{\text{sidereal}} \Omega})$$

Detailed description in
gr-qc/0510096

$$Q_{t_{\text{sidereal}} \Omega}(f) \propto \frac{H(f) \gamma_{t_{\text{sidereal}} \Omega}(f)}{P_1(f) P_2(f)}$$

$H(f)$ is the source spectrum

LIGO's Fourth Science Run (S4)

$$H_{\beta}(f) \propto \left(\frac{f}{100\text{Hz}} \right)^{\beta}$$

($\beta=-3$ corresponds to scale-invariant primordial perturbation spectrum)

FIG. 6: **S4 Result:** Map of the 90% confidence level Bayesian upper limit on H_{β} for $\beta = -3$. The upper limit varies between $1.2 \times 10^{-48} \text{Hz}^{-1} (100 \text{ Hz}/f)^3$ and $1.2 \times 10^{-47} \text{Hz}^{-1} (100 \text{ Hz}/f)^3$, depending on the position in the sky. All fluctuations are consistent with the expected noise.

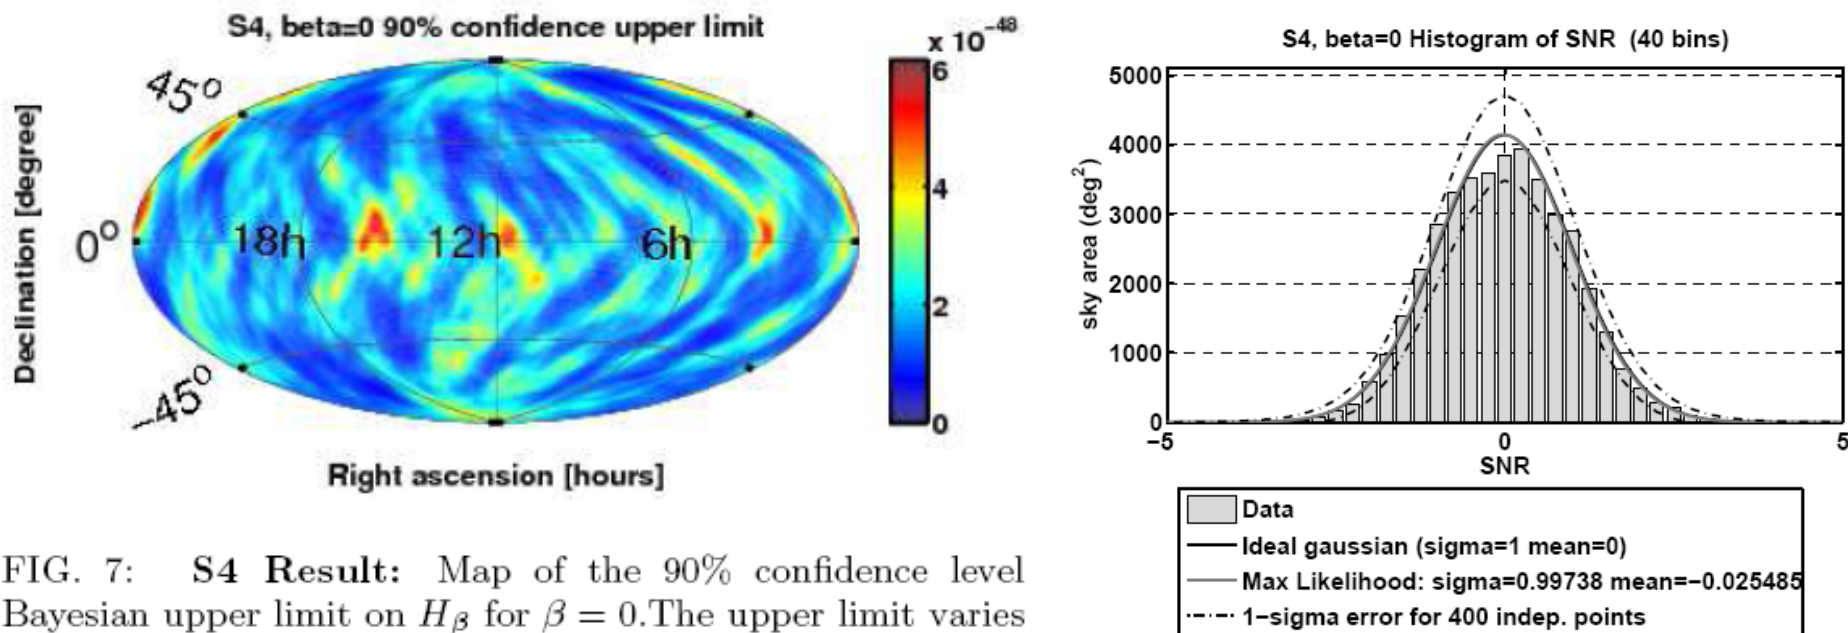

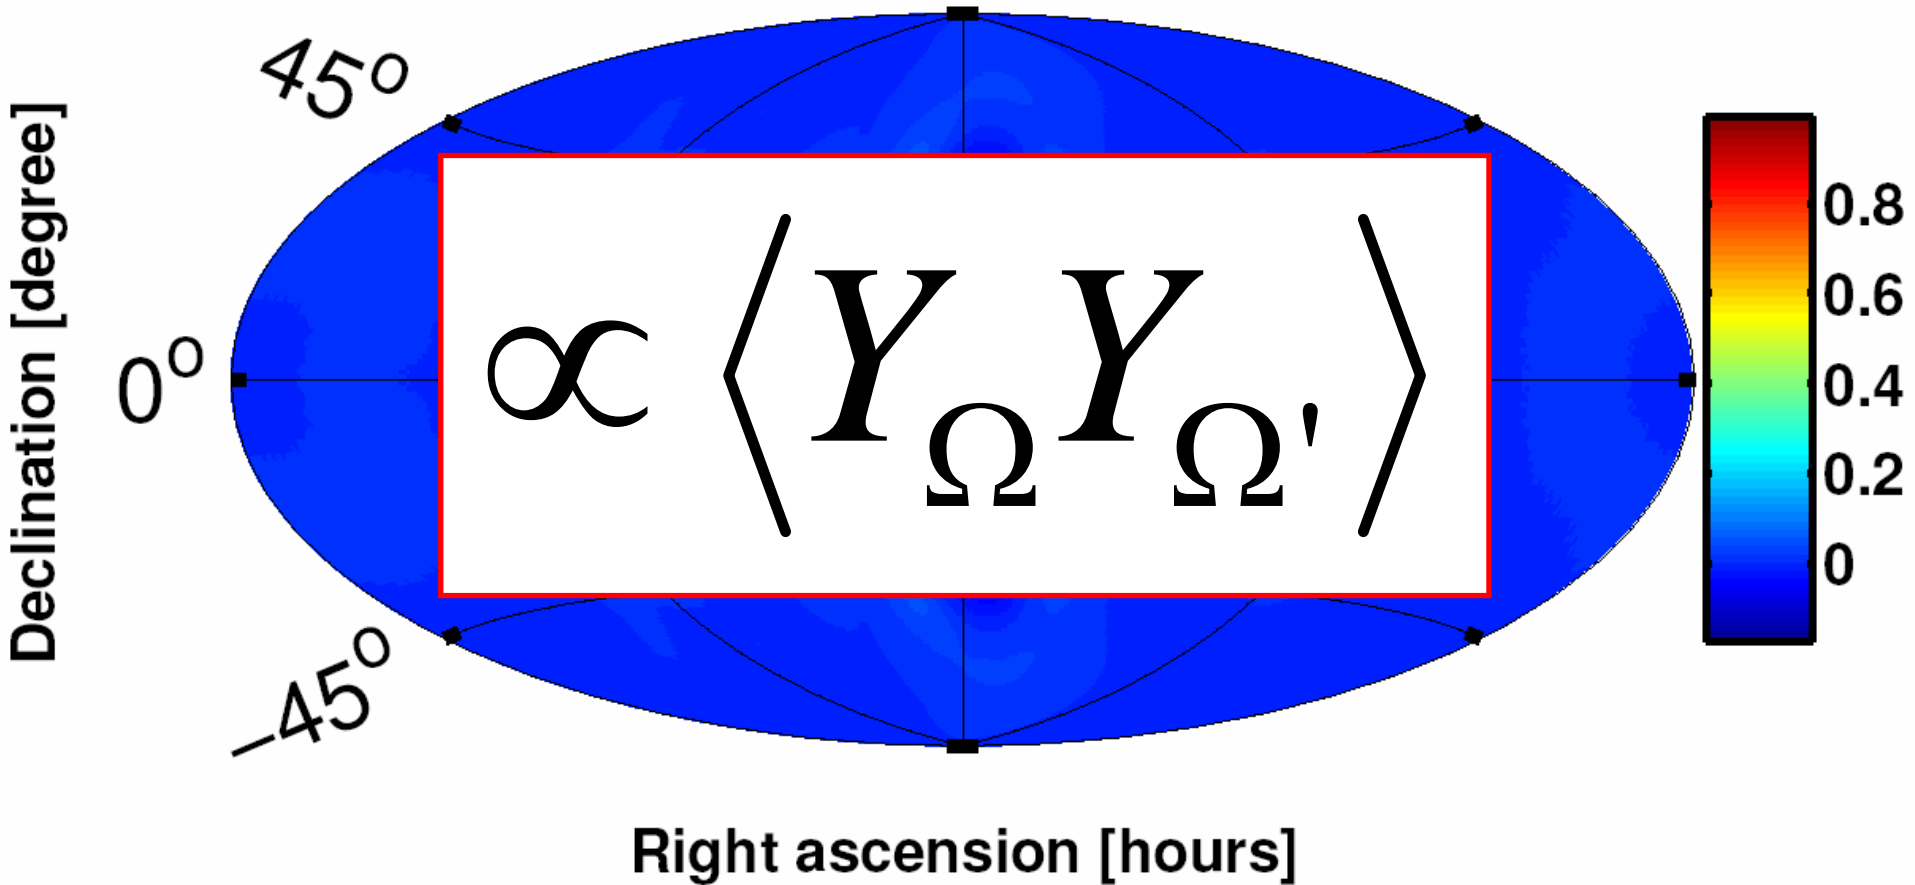

FIG. 7: S4 Result: Map of the 90% confidence level Bayesian upper limit on H_β for $\beta = 0$. The upper limit varies between $8.5 \times 10^{-49} \text{Hz}^{-1}$ and $6.1 \times 10^{-48} \text{Hz}^{-1}$ depending on the position in the sky.

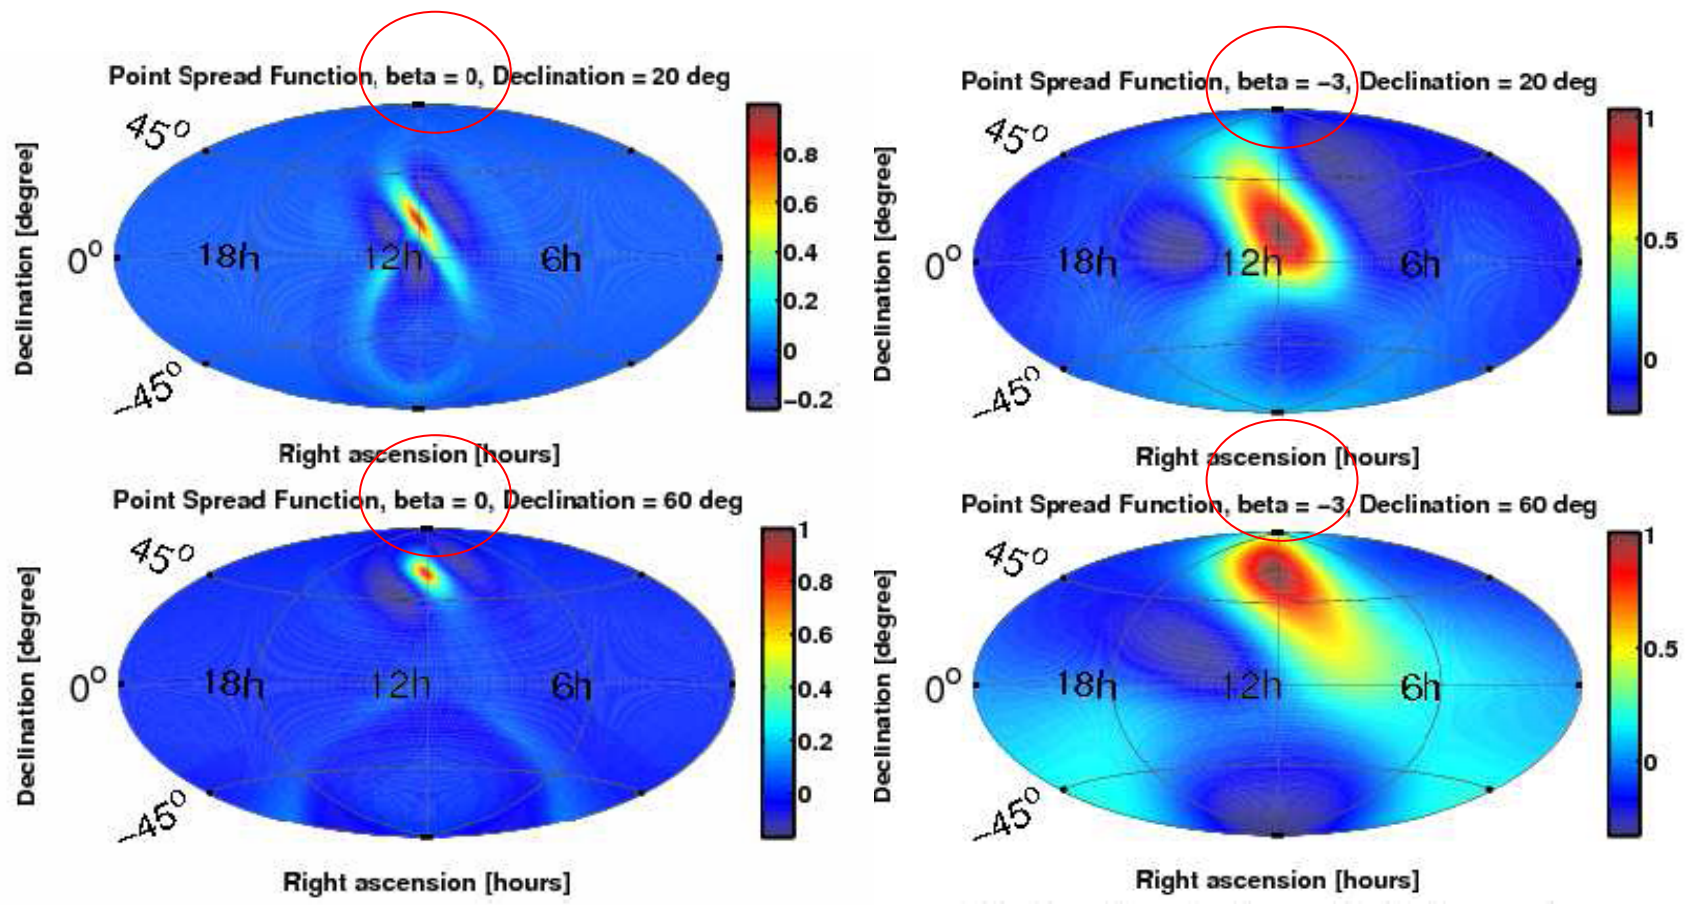

$$H_{90\%} = (0.85 - 6.1) \times 10^{-48} \text{Hz}^{-1}$$

But the maps are convolved

Point spread function

Point Spread Function

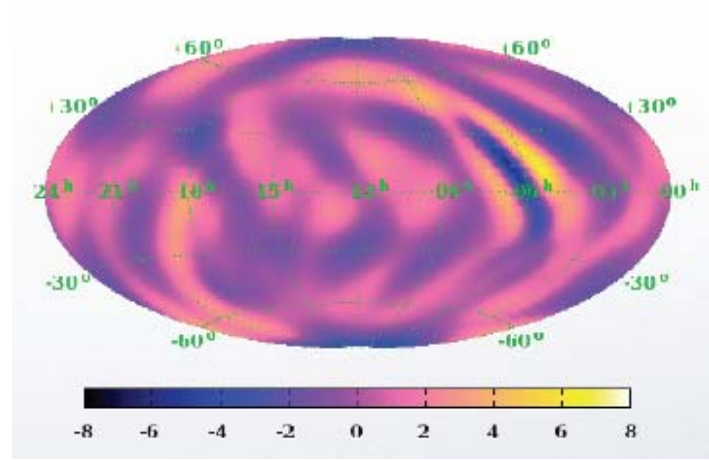

Deconvolving the map to get a Maximum Likelihood Estimation

Toy CMB map from Planck Simulator

Run through radiometer analysis to get “dirty” map; this convolves with point spread function

To deconvolve, invert the covariance matrix, which is large and varies with time & IFO sensitivity → computationally expensive

Or use a Spherical Harmonic Basis: Maximum Likelihood Estimation

- Rotational Symmetry → covariance = 0 for $m \neq m'$
- different l 's at the same m are correlated
- Symmetry broken due to diurnal sensitivity variations

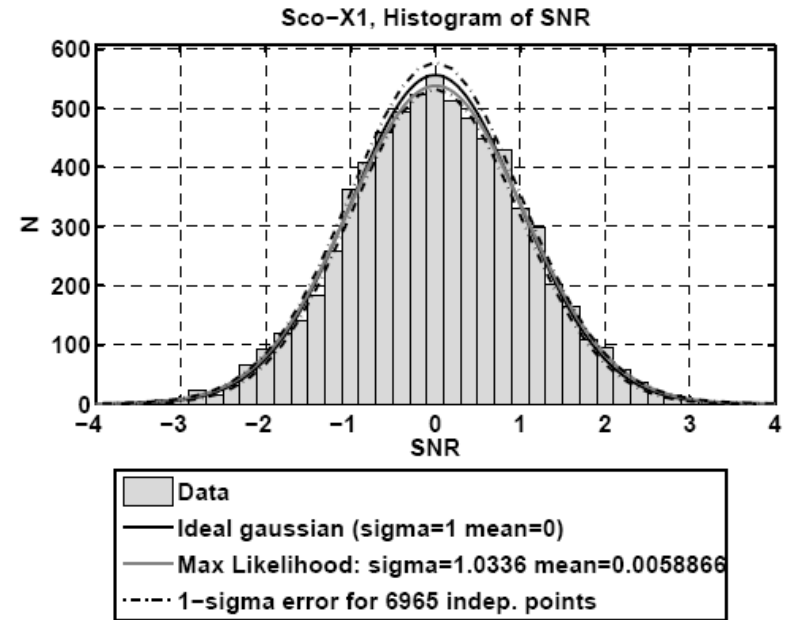

Advantage of a smaller (tens instead of thousands), block diagonal, covariance matrix → lower computational cost.

Being actively pursued by the stochastic analysis group.

Covariance matrix

Narrowband Radiometer Sco-X1 (brightest LMXB), S4

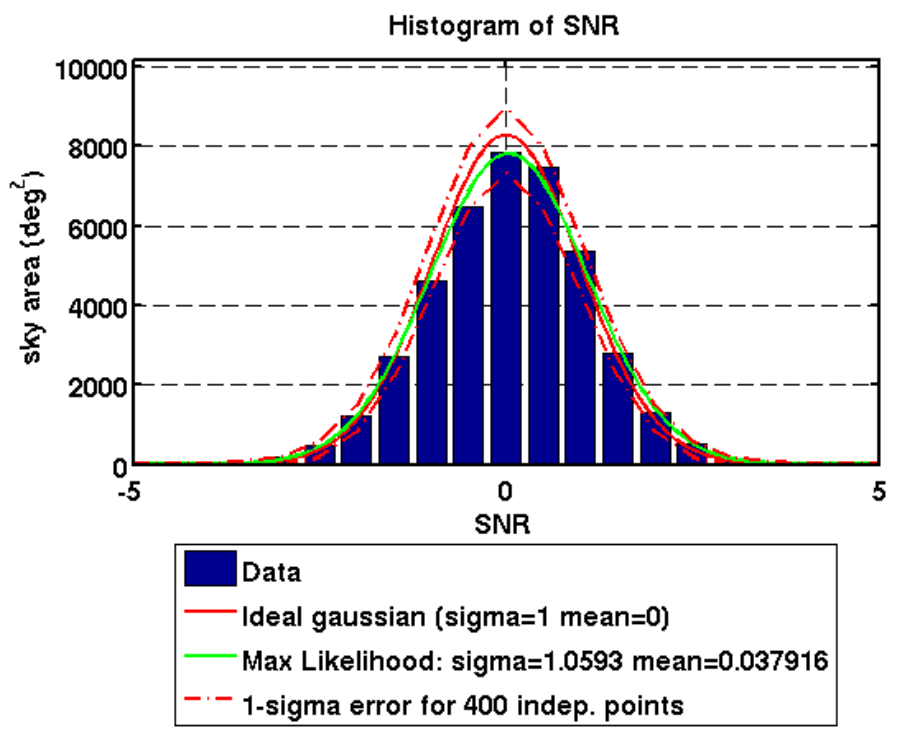

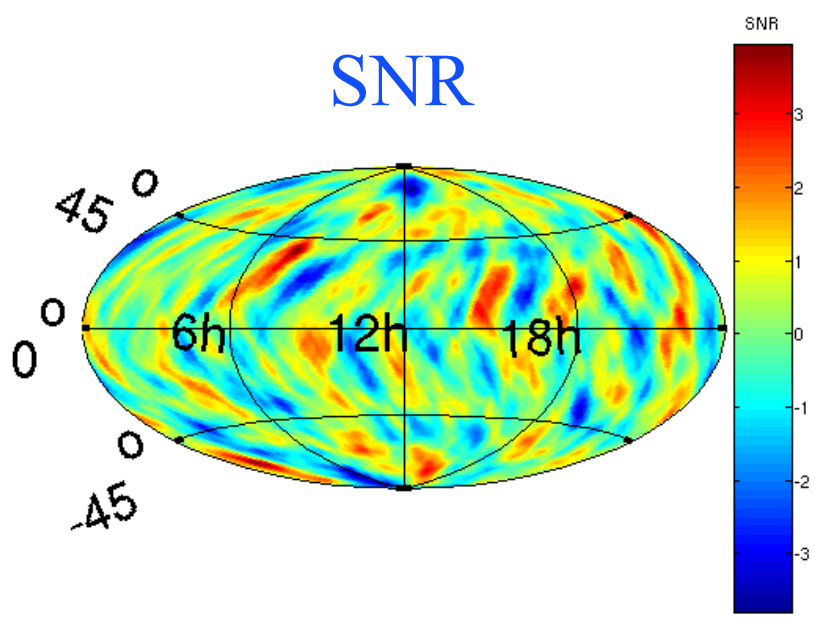

This is currently the best published limit on the gravitational wave flux coming from the direction of Sco-X1

Consistent with no signal

FIG. 9: S4 Result for Sco-X1: The 90% confidence Bayesian upper limit as a function of frequency - marginalized over the calibration uncertainty. The standard deviation (one sigma error bar) is shown in blue.

Blinded Data from S5

time shift the detector streams by more than the light travel time between detectors → no true gw signal remains

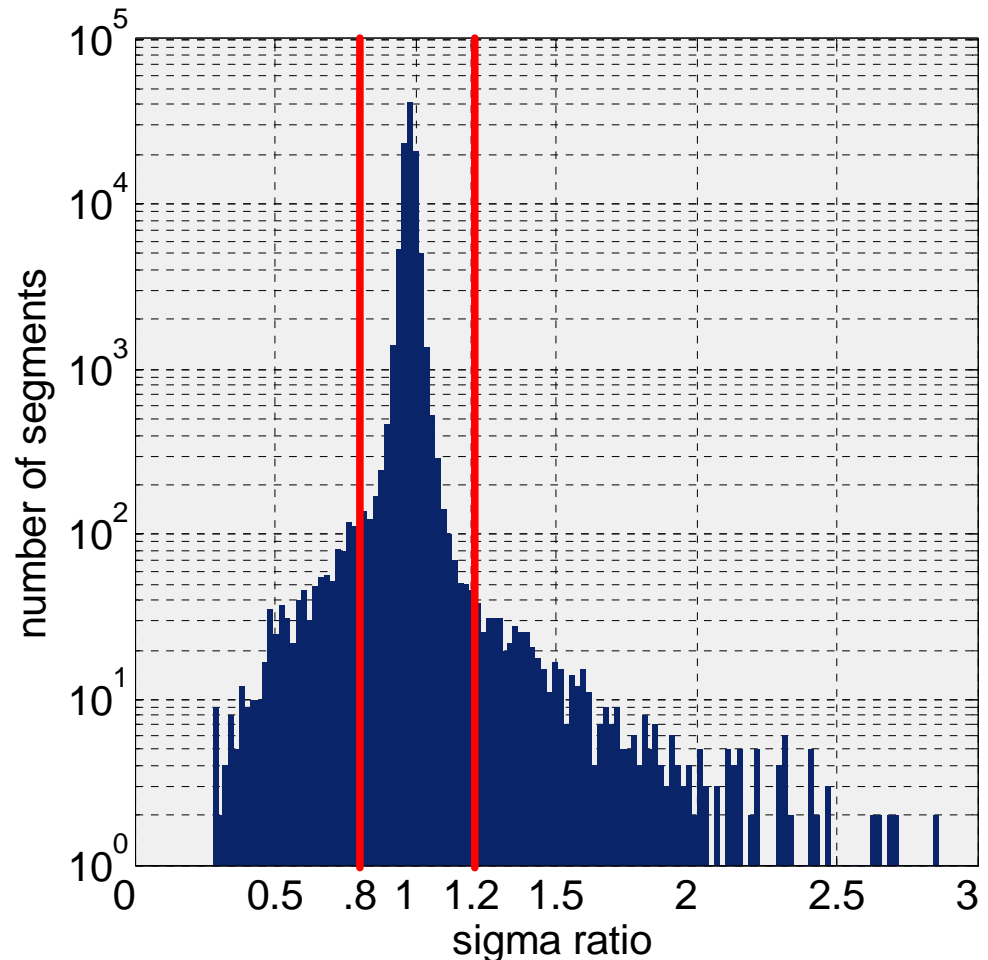

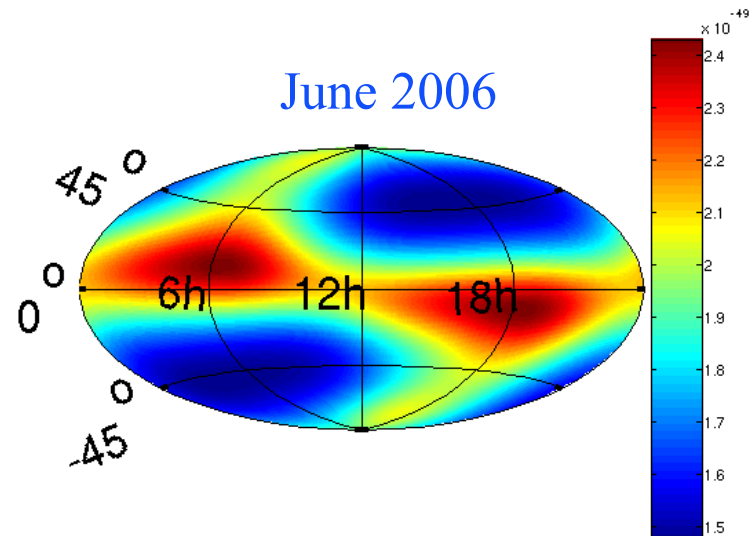

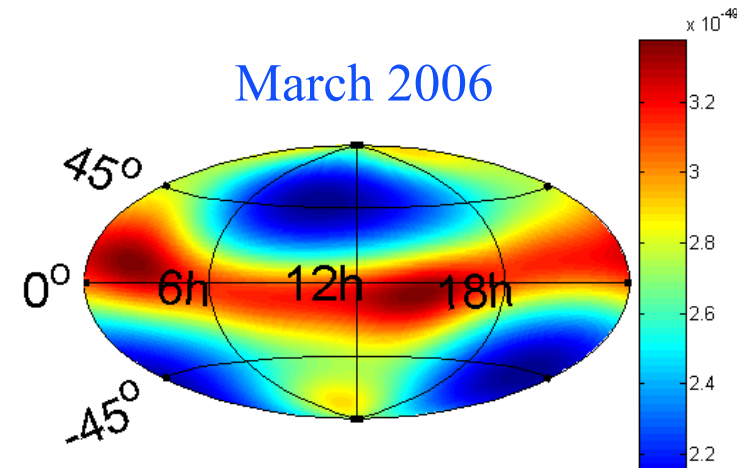

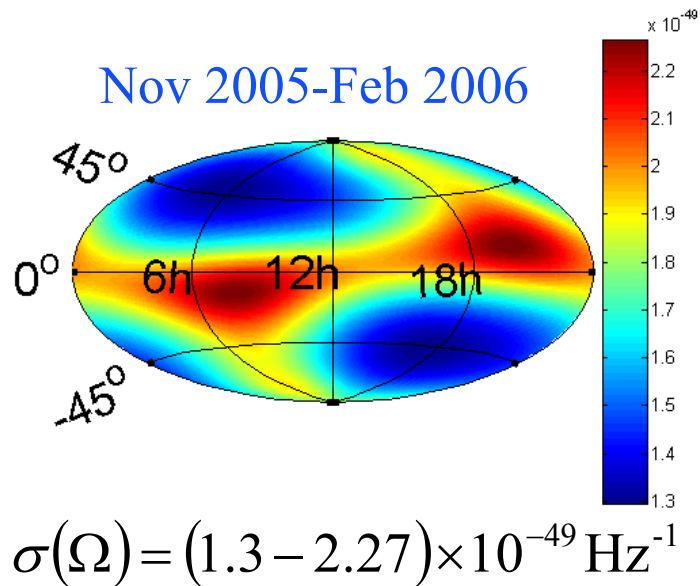

S5 result should be at least 10x better than S4 result

Detector Noise Non-stationarity: The Sigma Ratio Data Quality Cut

- Don't include any 60 second segments whose PSD gives a 20% larger sigma than neighboring PSD's to reduce effects of nonstationarity.
- This rejects 1.80% of the data
- 1st 4 months of S5 (blind)

Because the IFOs still work better at night, the region of best sensitivity moves across the sky as the earth goes around the sun

Another detection method: autocorrelation at each declination

- NOT a standard 2-point correlation function
 - Can't because of variability of point spread function with sky position
- $X(\Delta RA)$ at each declination (integral is over RA)
- Y_i 's are point estimates of GW strain
- w_i 's are statistical weights of each point on the sky (1st attempt: use reciprocal of theoretical sigma)
- Overall normalization is $X(0)$

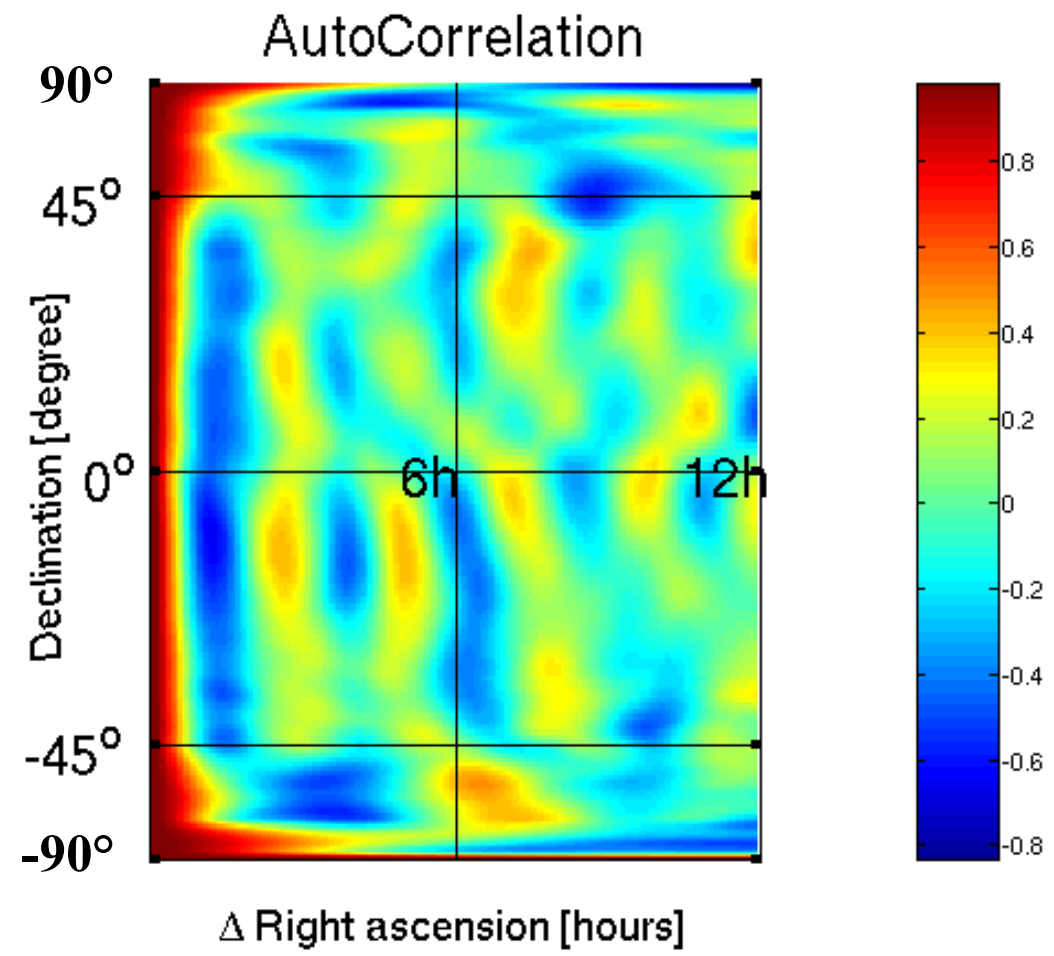

For all i, j separated by ΔRA

$$X(\Delta RA) = \sum_{i, j} w_i Y_i Y_j w_j$$

$$w_i = \frac{\langle \sigma \rangle_i}{\sigma_i}$$

Autocorrelation at each declination

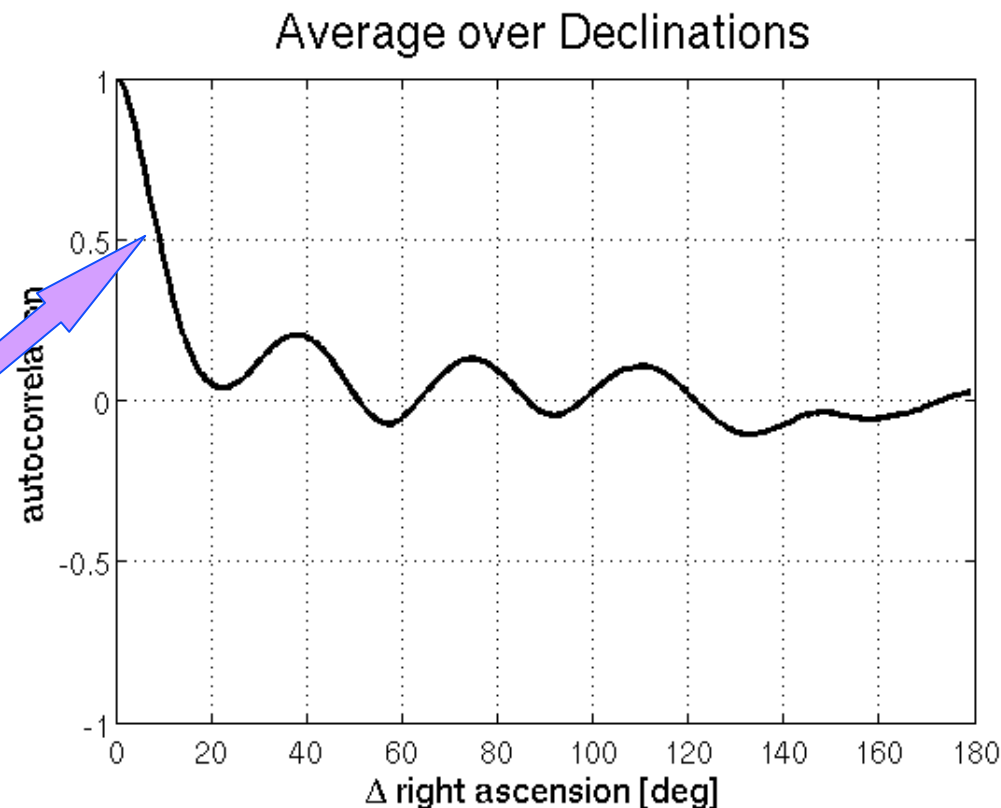

- Simulated data
- $H(f) = \text{const}$
- Working on a “detection metric”— what quantifies absence/presence of signal?

Average the autocorrelations at each declination, over all declinations

In the absence of signal, this can tell us about the resolving power of the instrument; consistent with other estimates.

$$\frac{\lambda}{D} \begin{matrix} 500 \text{ Hz} \\ \Rightarrow \\ 3000 \text{ km} \end{matrix} \Rightarrow 11^\circ$$

diffraction limited gw astronomy

The Near Future

- Projected sensitivity increase and longer run time means we should surpass BBN bound during S5, for the isotropic analysis (integrating over the whole sky).
- Conduct narrowband searches from more directions (Virgo cluster, galactic plane)
- Continue development of maximum likelihood analysis, in both point-source (pixel) basis and spherical harmonic basis.

The End

The End

Data Analysis Flow
